Chubb Addresses Growing Cyber Risks with a Flexible and Sustainable Approach

Policyholders may tailor cyber insurance coverage levels for Widespread Events, Ransomware Encounters, and Neglected Software Vulnerabilities.

Widespread Events

The world is becoming more digitized and interconnected every year. Widely used software programs, communication platforms, and technology platforms are leveraged and often relied upon by thousands or millions of companies. A single attack upon and/or failure of one of these widely used platforms or technologies could create an aggregation risk that exceeds the insurance industry's capacity to insure. In order to provide policyholders with coverage clarity and market stability, Chubb provides affirmative and specific limits, retentions, and coinsurance for such "Widespread Events."

Types of Widespread Event perils covered include:

- Widespread Software Supply Chain Exploits
 These are attacks that allow bad actors to enter systems through trusted, certified software and are effectively a Trojan horse to a system.
- Widespread Severe Zero-Day Exploits
 These are attacks arising from certain software vulnerabilities that are known by cyber criminals but not yet by anyone else vulnerabilities that can be easily exploited, are severe, and often lack protection.

- Widespread Severe Known
 Vulnerability Exploits
 These are attacks arising from
 severe known software
 vulnerabilities that are not
 patched. The vulnerabilities
 are considered severe because
 they are easy to exploit, can be
 deployed remotely with limited
 access privileges, and can
 result in significant adverse
 impact.1
- All Other Widespread Events Certain types of cyber attacks can be carried out concurrently or automatically against a wide number of victims, ultimately causing a catastrophic cyber event. The Internet and some telecommunications services have risen to the level of critical societal infrastructure, and some large cloud computing firms are so widely used that an outage could impact the operations of thousands or even millions of companies.

Real-World Examples of Widespread Event Perils:

- Widespread Software Supply Chain Exploit: Solorigate (2020), NotPetya (2017)
- Widespread Zero-Day Exploit: Hafnium (2021)
- Widespread Severe Known Vulnerability Exploit: MSSP Attack (2021)
- Other Widespread Event: Virginia Cloud Outage (2020)

The Widespread Event Endorsement provides concise and sensible loss adjustment rules, including:

- Incident response expenses do not erode Widespread Event limits until after it is determined that an incident is a Widespread Event, with no return of expenses incurred prior to that determination.
- Policyholders can opt out of sharing certain types of investigatory data when it is mutually agreed that an incident is a Widespread Event.
- All cyber incidents are categorized as either Limited-Impact Events (e.g., a local event with "business as usual" loss rules) or Widespread Events (e.g., a systematic event with structural loss adjustment differences such as limit, retention, and coinsurance), enabling policyholders to purchase the coverage that best meets the needs of their organization.

Ransomware Encounters

Ransomware attacks have grown dramatically in both frequency and severity. The loss implications to policyholders are far broader than just the value of the ransom amount. Whether the ransom is paid or not, policyholders often incur legal costs, forensic investigatory expenses, business interruption loss, digital data recovery costs, and, potentially, liability and legal defense costs.

The Ransomware Encounter Endorsement allows for tailoring of coverage limits, retention, and coinsurance for losses incurred as the result of a Ransomware Encounter.

Neglected Software Vulnerabilities

Keeping software up to date is an important aspect of good cyber risk hygiene. Many losses can be prevented by patching vulnerable software before cyber criminals have an opportunity to exploit it, but some organizations may not patch software right away. Sometimes there are legitimate reasons that software updates need to be tested before being rolled out, and compatibility, capacity, or simple logistics issues may prevent even a well-run information security organization from deploying patches within the first day or week after they become available. For that reason, Chubb provides policyholders with a 45-day grace period to patch software vulnerabilities that are published as Common Vulnerabilities and Exposures (CVEs) within the National Vulnerability Database operated by the U.S. National Institute for Standards and Technology (NIST).

The Neglected Software Exploit Endorsement provides coverage after the 45-day grace period expires, with the risk-sharing between the policyholder and insurer incrementally shifting to the policyholder, who takes on progressively more of the risk if the vulnerability is not patched at the 46-, 90-, 180-, and 365-day points.
